

ANTI-OBESE IMMUNOGENIC HYBRID POLYPEPTIDES AND ANTI-OBESE  
VACCINE COMPOSITION COMPRISING THE SAME

Technical Field

The present invention relates to an immunogenic  
5 hybrid polypeptide, which comprises an amino acid sequence  
of a mimetic peptide of a B cell epitope of apolipoprotein B-  
100 and in which a C-terminus of the mimetic peptide is fused  
to an N-terminus of a helper T cell epitope, and a vaccine  
composition for preventing or treating obesity comprising  
10 the same.

Background Art

Recently, arteriosclerosis and coronary  
atherosclerotic disease (CAD) have been gradually  
increasing in Korea due to a shift to Western dietary  
15 habits, and are the leading cause of increased mortality.  
Serum lipids causing these diseases include cholesterol,  
triglycerides (TG), free fatty acids and phospholipids.  
They form lipoproteins with apolipoproteins and are  
transported through the bloodstream. Among them, low  
20 density lipoproteins (LDL) function to transport mainly TG  
and cholesterol, and changes in LDL-cholesterol levels are  
indications of the prognosis of the diseases.

LDL-cholesterol, which is a major factor of lipid metabolism-associated diseases of adult people, binds to LDL receptors on the plasma membrane of cells in each tissue and is stored and used in the tissue. Alternatively, 5 LDL-cholesterol is taken up by scavenger cells and hydrolyzed, and free cholesterol is transferred to HDL along with apo E lipoprotein to be recycled in the liver, or is converted to bile salt to be discharged. During this process, the apolipoprotein performs very important 10 functions to maintain structural homeostasis of lipoproteins, serves as a cofactor of the enzyme lipoprotein lipase, and plays a critical role in binding to a specific receptor on the plasma membrane.

Apolipoprotein B-100 (Apo B-100) is a major protein 15 component of LDL, and is also present in IDL and VLDL. Thus, when antibodies in the blood are induced to recognize apo B-100, LDL clearance by phagocytes will easily occur. In this regard, some recent studies have been focused on the employment of vaccines to decrease plasma LDL- 20 cholesterol levels and reduce the incidence of arteriosclerosis. Antibodies induced by such anti-cholesterol vaccine therapy are IgM types which are considered to bind to VLDL, IDL and LDL, and such a strategy suggests the possibility of developing vaccines 25 for preventing and treating hypercholesterolemia and atherosclerosis (Bailey, et al., Cholesterol vaccines.

Science 264, 1067-1068, 1994; Palinski W et al., *Proc Natl Acad Sci U.S.A.* 92, 821-5, 1995; Wu R, de Faire U et al., *Hypertension*. 33, 53-9, 1999). Also, apolipoprotein B-100 is a huge protein molecule, which consists of 4560 amino acid residues, contains signal peptide of 24 amino acid residues and has a molecular weight of more than 500 kDa (Elovson J et al., *Biochemistry*, 24:1569-1578, 1985). Since apolipoprotein B-100 is secreted mainly by the liver and is an amphipathic molecule, it can interact with the lipid components of plasma lipoproteins and an aqueous environment (Segrest J. P et al., *Adv. Protein Chem.*, 45:303-369, 1994). Apolipoprotein B-100 stabilizes the size and structure of LDL particles and plays a critical role in controlling the homeostasis of plasma LDL-cholesterol through binding to its receptor (Brown MS et al., *Science*, 232:34-47, 1986).

Korean Pat. Laid-open Publication No. 2002-0018971, which was filed by the present inventors, describes a mimetic peptide of an epitope of apo B-100 having an anti-obesity effect. However, this publication only discloses that the mimetic peptide of the B cell epitope has an anti-obesity effect.

Prior to the present invention, there is no report of enhancing the immunogenicity of an apolipoprotein by fusing a B cell epitope of the apolipoprotein and a T cell epitope, except for an attempt to enhance immune responses by employing a protein carrier or adjuvant.

As described in U.S. Pat. No. 5,843,446, when luteinizing hormone releasing hormone (LHRH) is conjugated with a different protein to enhance the immunogenicity of LHRH, the majority of immune responses are directed to the carrier protein rather than to LHRH, leading to carrier-induced immune suppression. Thus, persistent effort is required for selecting additional materials and determining linkage patterns and linkage sites capable of enhancing the immunogenicity of B cell epitopes.

Many attempts to fuse a hapten with a carrier protein were made to enhance the immunogenicity of the hapten, but failed to obtain uniform enhancing effects. In particular, the linear linkage of a B cell epitope and a T cell epitope, like the present invention, resulted in loss of immunogenicity according to the orientation of the epitopes, the type of each epitope, and the like (Francis, M. J. et al., *Nature* 330:168-170, 1987), and the presence of a linker brought about reduced antigenicity (Partidos, C. et al., *Mol. Immunol.* 29:651-658, 1992). That is, there is no consistent rule applicable to design peptide vaccines, and the efficacy of designed vaccines is also not predictable. For the same reasons, when a highly hydrophobic PB1<sub>4</sub> peptide, which is an apo-B mimetic peptide, is fused with a T cell epitope, an antigenic region can be internalized into the fusion protein, leading to a decrease in its ability to induce antibody responses.

Based on this background, the present inventors made various attempts to enhance the immunogenicity of PB1<sub>4</sub>, which is a mimetic peptide of a B cell epitope of apolipoprotein B-100 having an anti-obesity effect. As a result, a hybrid polypeptide, in which an N-terminus of a helper T cell epitope is fused to a C-terminus of the mimetic peptide, displayed an excellent immunoenhancing effect, indicating that it is effective for preventing or treating obesity. It was an unexpected result since hybrid polypeptides displays excellent anti-obesity activity without inducing immune responses that neutralize beneficial activities or effects of the B cell epitope of apolipoprotein B-100 or without causing harmful side effects.

#### 15 Disclosure of the Invention

In one aspect, the present invention provides an immunogenic hybrid polypeptide, which comprises an amino acid sequence of a mimetic peptide of a B cell epitope of apolipoprotein B-100 and in which a C-terminus of the mimetic peptide is fused to an N-terminus of a helper T cell epitope.

In another aspect, the present invention provides a vaccine for preventing or treating obesity, comprising an immunogenic hybrid polypeptide, which comprises an amino

acid sequence of a mimetic peptide of a B cell epitope of apolipoprotein B-100 and in which a C-terminus of the mimetic peptide is fused to an N-terminus of a helper T cell epitope.

5           In a further aspect, the present invention provides a recombinant vector comprising a gene encoding the immunogenic hybrid polypeptide, a transformant comprising the recombinant vector, and a method of producing the hybrid polypeptide by culturing a host cell transformed  
10           with the recombinant vector.

#### Brief Description of the Drawings

The above and other objects, features and other advantages of the present invention will be more clearly understood from the following detailed description taken in  
15           conjunction with the accompanying drawings, in which:

FIG. 1 shows a process of constructing pB1<sub>4</sub>T;

FIG. 2 shows the results of digestion of pB1<sub>4</sub>T with restriction enzymes;

FIG. 3 shows a DNA sequence of pB1<sub>4</sub>T and an amino  
20           acid sequence predicted therefrom;

FIG. 4 shows the results of SDS-PAGE analysis for PB1<sub>4</sub>T expression in a transformed *Escherichia coli* strain, M15/pB1<sub>4</sub>T, which has been treated with IPTG to induce PB1<sub>4</sub>T expression, wherein the expressed recombinant PB1<sub>4</sub>T is

indicated by an arrow (M: prestained protein size marker;  
lane 1: *E. coli* M15 not induced with IPTG; and lanes 3 to  
7: IPTG-induced *E. coli* M15/pB1<sub>4</sub>T, collected 1, 2, 3, 4 and  
5 hrs, respectively, after IPTG induction);

5           FIG. 5 shows the results of SDS-PAGE analysis for  
PB1<sub>8</sub> expression in a transformed *Escherichia coli* strain,  
M15/pB1<sub>8</sub>, which has been treated with IPTG to induce PB1<sub>8</sub>  
expression, wherein the expressed recombinant PB1<sub>8</sub> is  
indicated by an arrow (M: prestained protein size marker;  
10       lane 1: *E. coli* M15 not induced with IPTG; and lanes 3 to  
7: IPTG-induced *E. coli* M15/pB1<sub>8</sub>, collected 1, 2, 3, 4 and 5  
hrs, respectively, after IPTG induction);

FIG. 6 shows the results of SDS-PAGE analysis of the  
centrifugal supernatant (lane 1) and pellet (lane 2) of an  
15       *E. coli* lysate, wherein expressed PB1<sub>4</sub>T is indicated by an  
arrow and is found in the pellet;

FIG. 7 shows the results of SDS-PAGE analysis of an  
*E. coli* lysate (lane 1: whole lysate; lane 2: centrifugal  
supernatant; lane 3: centrifugal pellet), wherein expressed  
20       PB1<sub>8</sub> is indicated by an arrow and is found in the pellet;

FIG. 8 shows the results of Western blotting for  
purified PB1<sub>4</sub>T with a rabbit anti-PB1<sub>4</sub> antibody (A) and an  
anti-preS2 monoclonal antibody (B) (lane 1: *E. coli* M15;  
lane 2: *E. coli* M15/pB1<sub>4</sub>T not induced with IPTG; lane 3:  
25       IPTG-induced *E. coli* M15/pB1<sub>4</sub>T, collected 3 hrs after IPTG  
induction);

FIG. 9 shows the PBl<sub>4</sub> elution profile resulting from Ni-NTA affinity chromatography according to a linear imidazole gradient;

FIG. 10 shows the PBl<sub>4</sub>T elution profile resulting from Ni-NTA affinity chromatography according to a linear imidazole gradient;

FIG. 11 shows the PBl<sub>8</sub> elution profile resulting from Ni-NTA affinity chromatography according to a linear imidazole gradient;

FIG. 12 shows a process of constructing pTBl<sub>4</sub>;

FIG. 13 shows the results of Western blotting for purified PBl<sub>4</sub>, PBl<sub>4</sub>T and PTBl<sub>4</sub> with a mouse anti-preS2 monoclonal antibody and an HRP-conjugated goat anti-mouse IgG antibody (A) and with an anti-PBl<sub>4</sub> anti-serum and an HRP-conjugated goat anti-rabbit IgG antibody (B);

FIG. 14 shows a DNA sequence of TBl<sub>4</sub>/pQE30 and an amino acid sequence predicted therefrom;

FIG. 15 is a graph showing the body weight increment of SD white rats of normal, mock and vaccinated groups, wherein the normal group (■) was injected with PBS, the mock group (▲) with ovalbumin, a vaccinated group (◆) with ovalbumin-conjugated PBl<sub>4</sub> (PBl<sub>4</sub>+OVA), and another vaccinated group (●) with PBl<sub>4</sub>T peptide, each peptide being injected three times at 2-week intervals, the arrows indicating time points at which vaccination was carried out;

FIG. 16 is a graph showing the changes in titers of

anti-PB1 antibodies induced by immunization of PB1<sub>4</sub>, PB1<sub>4</sub>T and PTB1<sub>4</sub>, respectively; and

FIG. 17 is a graph showing serum levels of triglyceride, HDL, LDL and total cholesterol.

5 Best Mode for Carrying Out the Invention

In one aspect, the present invention relates to an immunogenic hybrid polypeptide, which comprises an amino acid sequence of a mimetic peptide of a B cell epitope of apolipoprotein B-100 and in which a C-terminus of the  
10 mimetic peptide is fused to an N-terminus of a helper T cell epitope.

In a strategy to enhance the immunogenicity of an apolipoprotein, the present invention intends to provide an immunogenic hybrid polypeptide in which a T cell epitope is  
15 fused to a mimetic peptide of a B cell epitope of an apolipoprotein, especially apolipoprotein B-100 (apo B-100). When a T cell epitope was fused to a mimetic peptide of the B cell epitope of apo B-100, PB1<sub>4</sub> had improved ability to induce antibody responses and displayed vaccine  
20 efficacy for an extended period of time, and so had an excellent anti-obesity effect.

The term "mimetic peptide of an epitope", as used herein refers to a peptide that mimics a minimal part of the epitope, which is an epitope that is sufficiently

similar to a native epitope so that it can be recognized by an antibody specific to the native epitope, or that is able to increase an antibody to crosslink with a native epitope. A mimetic peptide is also called a mimotope. Such a mimetic peptide is advantageous because it is recognized as "non-self" *in vivo* and thus overcomes the problem of self-tolerance in immune responses. The mimetic peptide of a B cell epitope of apo B-100 is recognized by an antibody specifically binding to apo B-100. The antibody specifically binding to apo B-100 includes polyclonal and monoclonal antibodies, which specifically recognize and bind to apo B-100, and fragments thereof, for example, Fc, Fab and F(ab')<sub>2</sub>.

The mimetic peptide of a B cell epitope of apo B-100 according to the present invention includes an amino acid sequence selected from SEQ ID Nos. 1, 2 and 3. Thus, in a preferred aspect, the present invention relates to an immunogenic hybrid polypeptide, which includes an amino acid sequence selected from SEQ ID Nos. 1, 2 and 3, and in which a C-terminus of a peptide recognized by an antibody specifically binding to apo B-100 is fused to an N-terminus of a helper T cell epitope.

The present inventors isolated mimetic peptides (SEQ ID Nos. 1, 2 and 3) that are recognizable by a monoclonal antibody against apo B-100, Mab B9 or Mab B23, from a phage displayed peptide library by biopanning with the library.

The mimetic peptide of the epitope of apo B-100, which includes an amino acid sequence selected from SEQ ID Nos. 1, 2 and 3, may be in a monomeric form that is composed of a single copy of the amino acid sequence having  
5 any one of the SEQ ID Nos., or, to further enhance the immunogenicity of the mimetic peptide, may be in a multimeric form in which two or more, preferably three to eight, and more preferably three to six copies of the amino acid sequence having any one of the SEQ ID Nos. are linked.  
10 Most preferred is a tetramer (SEQ ID No. 4) in which four copies are linked. When the mimetic peptide is in a multimeric form, amino acid sequences each of which constitutes a monomer may be covalently linked directly or via a linker. When the amino acid sequences are linked via  
15 a linker, the linker may consist of one to five amino acid residues, which are selected from, for example, glycine, alanine, valine, leucine, isoleucine, proline, serine, threonine, asparagine, aspartic acid, cysteine, glutamine, glutamic acid, lysine and arginine. Preferred amino acids  
20 available in the linker may include valine, leucine, aspartic acid, glycine, alanine and proline. More preferably, taking the ease of gene manipulation into account, two amino acids selected from valine, leucine, aspartic acid, etc. may be linked and used as a linker. A  
25 preferred mimetic peptide is prepared by linking two or more copies of an amino acid sequence selected from SEQ ID

Nos. 1, 2 and 3 via the linker.

The term "T cell epitope", as used herein, refers to an amino acid sequence that is able to bind to MHC Class II molecules with a suitable efficiency and stimulate T cells or bind to T cells in a complex with MHC Class II. In this case, the T cell epitope is recognized by a specific receptor present on T cells, and functions to provide a signal requiring the differentiation of B cells to antibody-producing cells and induce cytotoxic T lymphocytes (CTL) to destroy target cells. The T cell epitope is not specifically limited as long as it stimulates T cells and strengthens immune responses, and a variety of proteins, peptides, etc. suitable for the purpose are available. With respect to the objects of the present invention, the T cell epitope is preferably a helper T cell epitope. Examples of the helper T cell epitope may include hepatitis B surface antigen helper T cell epitopes, Chlamydia trachomatis major outer membrane protein helper T cell epitopes, Plasmodium falciparum circumsporozoite helper T cell epitopes, Escherichia coli TraT helper T cell epitopes, Tetanus toxoid helper T cell epitopes, diphtheria toxoid helper T cell epitopes, Schistosoma mansoni triose phosphate isomerase helper T cell epitopes, measles virus F protein helper T cell epitopes, T cell epitope sequences derived from pertussis vaccines, BCG (Bacille Calmette-Guerin), polio vaccines, mumps vaccines, rubella vaccines, rabies

vaccines, purified protein derivatives of tuberculin, keyhole limpet hemocyanin, and fragments or combinations thereof. The T cell epitope may include an addition, deletion or substitution of a selected amino acid residue according to the specific purpose, and may be provided in a multimeric form in which two or more different T cell epitopes are linked. In an embodiment of the present invention, a surface antigen of hepatitis B virus is used. The genome of hepatitis B virus (HBV) is 3.2 kb in length, possesses the information for four important proteins and contains four open reading frames, S gene (surface antigen protein), C gene (core protein), P gene (DNA polymerase) and X gene. The S gene is divided into an S region encoding HBsAg and a preS region. The preS region is divided into preS1 encoding 108 or 119 amino acids according to HBV strains and preS2 encoding 55 amino acids regardless of subtype. The HBV preS2 protein activates helper T cells during in vivo immune responses, thereby stimulating the formation of an antibody against HBV.

The term "hybrid polypeptide", as used herein, generally indicates a peptide in which heterogenous peptides having different origins are linked, and in the present invention, refers to a peptide in which a B cell epitope and a T cell epitope are linked. This hybrid polypeptide may be obtained by chemical synthesis or expression and purification through genetic recombination

after each partner is determined. Preferably, a hybrid gene, in which a gene sequence encoding a B cell epitope is linked to another gene sequence encoding a T cell epitope, is expressed in a cell expression system. In such a hybrid polypeptide, the B cell epitope and the T cell epitope may be linked directly or by means of a connector, such as a linker. When a linker is used, it should not negatively affect the induction of immune responses by the hybrid polypeptide.

The term "polypeptide", as used herein, is a term including a full-length amino acid chain in which residues including two or more amino acids are conjugated by covalent peptide bonds, and includes dipeptides, tripeptides, oligopeptides and polypeptides. In particular, in the present invention, the polypeptide means a hybrid polypeptide in which two or more peptides, in which several to several tens of amino acids are covalently bonded, are linked with each other. The hybrid polypeptide of the present invention is a polypeptide in which two or more peptides, for example, a B cell epitope and a T cell epitope, are linked. Each peptide sequence comprising the polypeptide includes a sequence corresponding to the aforementioned epitope, and may further include a sequence adjacent to the epitope. These peptides may be made of L- or D-amino acids, or may be in various combinations of amino acids in two different configurations. The hybrid

polypeptide of the present invention may be entirely composed of an antigenic region including the aforementioned B cell epitope, T cell epitope and a certain sequence adjacent thereto, and may further include an  
5 additional sequence. However, this additional sequence preferably should not reduce the overall immunogenicity. Such an additional sequence is exemplified by a linker sequence.

The term "immunogenicity", as used herein, refers to  
10 the ability to induce both cellular and humoral immune responses to defend the body against impurities. A material inducing such immune responses is called an immunogen. The present invention employs a polypeptide having both a B cell epitope and a T cell epitope, which are immunogenic  
15 materials.

The present inventors linked a C-terminus of PB1<sub>4</sub>, which is a tetrameric apo B-100 mimetic peptide that is an anti-obesity functional peptide having a B cell epitope but deficient in a T cell epitope, to a portion (T fragment) of  
20 HBV preS2 having a T cell epitope, thereby generating a gene fragment for the expression of PB1<sub>4</sub>T (FIG. 1). A PB1<sub>4</sub> fragment was obtained using BamHI and XhoI, and a T fragment was obtained using SalI and HindIII. The PB1<sub>4</sub>T gene fragment was inserted into a pQE30 vector and  
25 transformed into *E. coli* JM109. An emerged colony was analyzed by restriction mapping (FIG. 2) and DNA sequencing

(FIG. 3), and was found to be a correct clone in which the B cell epitope is linked to the T cell epitope. This clone was designated "pB1<sub>4</sub>T". The pQE30 vector used for the expression of PBl<sub>4</sub>T and PBl<sub>8</sub> initiates protein expression from its internal start codon along with six histidine residues for the convenience of protein purification, followed by an enterokinase cleavage site. The thus expressed PBl<sub>4</sub>T is 16.2 kDa, and PBl<sub>8</sub> is 16.5 kDa. Protein expression was investigated by subjecting samples collected at given time points to SDS-PAGE analysis (FIGS. 4 and 5).

Thus, an immunogenic hybrid polypeptide of SEQ ID No. 9, in which a tetrameric apo B-100 mimetic peptide is linked to an HBV surface antigen preS2, may be provided in the practice of the present invention.

The immunogenic hybrid polypeptide of the present invention may be produced by chemical synthesis or genetic recombination. Preferably, the present hybrid polypeptide may be produced by transforming a host cell with a recombinant vector and isolating and purifying a polypeptide expressed by the host cell.

Thus, in another aspect, the present invention provides a recombinant vector comprising a gene encoding the immunogenic hybrid polypeptide, and a host cell transformed with the recombinant vector.

In a further aspect, the present invention provides a method of producing the immunogenic hybrid polypeptide by

culturing a host cell transformed with the recombinant vector.

A process of producing the immunogenic hybrid polypeptide of the present invention by genetic  
5 recombination comprises the following four steps.

The first step is to insert a gene encoding the hybrid polypeptide into a vector to construct a recombinant vector. A vector into which foreign DNA is introduced may be a plasmid, a virus, a cosmid, or the like. The  
10 recombinant vector includes a cloning vector and an expression vector. A cloning vector contains a replication origin, for example, a replication origin of a plasmid, phage or cosmid, which is a "replicon" at which the replication of an exogenous DNA fragment attached thereto  
15 is initiated. An expression vector was developed for use in protein synthesis. A recombinant vector serves as a carrier for a foreign DNA fragment inserted thereto, which typically means a double-stranded DNA fragment. The term "foreign DNA", as used herein, refers to DNA derived from a  
20 heterogeneous species, or a substantially modified form of native DNA from a homogenous species. Also, the foreign DNA includes a non-modified DNA sequence that is not expressed in cells under normal conditions. In this case, a foreign gene is a specific target nucleic acid to be transcribed,  
25 which encodes a polypeptide. The recombinant vector contains a target gene that is operably linked to

transcription and translation expression regulatory sequences, which exert their functions in a selected host cell, in order to increase expression levels of the transfected gene in the host cell. The recombinant vector  
5 is a genetic construct that contains essential regulatory elements to which a gene insert is operably linked to be expressed in cells of an individual. Such a genetic construct is prepared using a standard recombinant DNA technique. The type of the recombinant vector is not  
10 specifically limited as long as the vector expresses a target gene in a variety of host cells including prokaryotes and eukaryotes and functions to produce a target protein. However, preferred is a vector which is capable of mass-producing a foreign protein in a form  
15 similar to a native form while possessing a strong promoter to achieve strong expression of the target protein. The recombinant vector preferably contains at least a promoter, a start codon, a gene encoding a target protein, a stop codon and a terminator. The recombinant vector may further  
20 suitably contain DNA coding a signal peptide, an enhancer sequence, 5'- and 3'-untranslational regions of a target gene, a selection marker region, a replication unit, or the like.

The second step is to transform a host cell with the  
25 recombinant vector and culture the host cell. The recombinant vector is introduced into a host cell to

generate a transformant by a method described by Sambrook, J. et al., Molecular Cloning, A Laboratory Manual (2nd Ed.), Cold Spring Harbor Laboratory, 1. 74, 1989, the method including a calcium phosphate or calcium chloride/rubidium chloride method, electroporation, electroinjection, chemical treatments such as PEG treatment, and gene gun. A useful protein can be produced and isolated on large scale by culturing a transformant expressing the recombinant vector in a nutrient medium.

Common media and culture conditions may be suitably selected according to host cells. Culture conditions, including temperature, pH of a medium and culture time, should be maintained suitable for cell growth and mass production of a protein of interest. Host cells capable of being transformed with the recombinant vector according to the present invention include both prokaryotes and eukaryotes. Host cells having high introduction efficiency of DNA and having high expression levels of an introduced DNA may be typically used. Examples of host cells include known prokaryotic and eukaryotic cells such as *Escherichia* sp., *Pseudomonas* sp., *Bacillus* sp., *Streptomyces* sp., fungi and yeast, insect cells such as *Spodoptera frugiperda* (Sf9), and animal cells such as CHO, COS 1, COS 7, BSC 1, BSC 40 and BMT 10. *E. coli* may be preferably used.

The third step is to induce the hybrid polypeptide to express and accumulate. In the present invention, the

inducer IPTG was used for the induction of peptide expression, and induction time was adjusted to obtain maximal protein yield.

5 The final step is to isolate and purify the hybrid polypeptide. Typically, a recombinantly produced peptide can be recovered from a medium or a cell lysate. When the peptide is in a membrane-bound form, it may be liberated from the membrane using a suitable surfactant solution (e.g., Triton-X 100) or by enzymatic cleavage. Cells used  
10 in the expression of the hybrid peptide may be destroyed by a variety of physical or chemical means, such as repeated freezing and thawing, sonication, mechanical disruption or a cell disrupting agent, and the hybrid peptide may be isolated and purified by commonly used biochemical  
15 isolation techniques (Sambrook et al., Molecular Cloning: A laboratory Manual, 2nd Ed., Cold Spring Harbor Laboratory Press, 1989; Deutscher, M., Guide to Protein Purification Methods Enzymology, Vol. 182. Academic Press. Inc., San Diego, CA, 1990). Non-limiting examples of the biochemical  
20 isolation techniques include electrophoresis, centrifugation, gel filtration, precipitation, dialysis, chromatography (ion-exchange chromatography, affinity chromatography, immunosorbent affinity chromatography, reverse phased HPLC, gel permeation HPLC), isoelectric  
25 focusing, and variations and combinations thereof.

In detail, in the present invention, the PB1<sub>4</sub>T gene

fragment was ligated with a pQE30 vector and transformed into *E. coli*. The pQE30 vector is useful for mass-producing proteins in *E. coli* because it contains a promoter element consisting of the phage T5 promoter and a *lac* operator system using IPTG as an inducer. The expression of PB1<sub>4</sub>T was confirmed by Western blotting using two antibodies recognizing PB1<sub>4</sub>T, a rabbit anti-PB1<sub>4</sub> polyclonal antibody and a mouse anti-preS2 monoclonal antibody, as primary antibodies, and expressed proteins were then purified. PB1<sub>4</sub> and PB1<sub>4</sub>T were denatured with 8 M urea because they are insoluble, and were purified by affinity chromatography using Ni-NTA resin for histidine-tagged proteins.

Rats were immunized with the expressed and purified polypeptide, and were assessed for an increase in body weight of rats, serum antibody titers and changes in serum lipid profiles. As a result, compared to a normal group or a group vaccinated with a non-fusion mimetic peptide, a group vaccinated with the hybrid polypeptide showed suppressed weight gain, high titers and extended retention of an antibody against the mimetic peptide, and decreased serum levels of TG and LDL-cholesterol.

There is no consistent rule applicable to peptide vaccine design, and the efficacy of designed vaccines is also unpredictable. For the same reasons, when a highly hydrophobic PB1<sub>4</sub> peptide is fused with a T cell epitope that is a heterogeneous peptide, an antigenic region can be

internalized into the fusion protein, leading to a decrease in its ability to induce antibody responses. In this difficult situation to deduce the fusion results, the present inventors designed the hybrid polypeptide in which  
5 a mimetic peptide of the apo B-100 epitope is linked to a T cell epitope, and demonstrated that the hybrid polypeptide has increased immunogenicity that results in increased anti-obesity effect.

The immunogenicity of an artificially synthesized  
10 hybrid polypeptide and a vaccine comprising the same is achieved when a B cell epitope and a helper T cell epitope are present at the same time. Also, the efficacy of the vaccine may be determined according to the orientation of the B cell epitope and the helper T cell epitope. That is,  
15 the ability of the hybrid polypeptide to induce antibody responses may vary depending on the helper T cell epitope being located at an N-terminus or a C-terminus of the B cell epitope (Partidos, C, Stanley, C, and Steward, M, The effect of orientation of epitope on the immunogenicity of  
20 chimeric synthetic peptides representing measles virus protein sequences, Molecular Immunology, 29(5), 651-658, 1992).

In order to investigate the effect of the orientation of the B cell epitope and the helper T cell epitope on the  
25 induction of immune responses, the present inventors prepared a TB1<sub>4</sub> gene fragment by linking an N-terminus of

PB1<sub>4</sub> to a T fragment (FIG. 12), unlike the preparation of the B1<sub>4</sub>T gene fragment involving linking a C-terminus of PB1<sub>4</sub> to a T fragment. In detail, a pTB1<sub>4</sub> vector was constructed according to a method described in Example 9, transformed into *E. coli* M15, and expressed therein. The expressed hybrid polypeptide PTB1<sub>4</sub>, which has a His tag, was purified by affinity chromatography using Ni-NTA His-bound resin.

In order to compare PTB1<sub>4</sub> and PB1<sub>4</sub>T for their ability to induce antibody responses and immunogenicity, SD rats were immunized with each of the polypeptides, and blood samples were collected. Compared to PB1<sub>4</sub>, PTB1<sub>4</sub> had enhanced ability to induce antibody responses, and the retention period of the serum antibody against PTB1<sub>4</sub> was prolonged. However, these improvements upon immunization with PTB1<sub>4</sub> were remarkably found to be about 50-60% lower than with PB1<sub>4</sub>T (FIG. 16). The same results were found in the suppression of body weight gain of the rats (Table 2). These results indicate that the PB1<sub>4</sub>T polypeptide, prepared by linking a C-terminus of PB1<sub>4</sub> to a T fragment, has much stronger immunogenicity and anti-obesity effects.

Thus, in yet another aspect, the present invention relates to a vaccine for preventing or treating obesity, comprising an immunogenic hybrid polypeptide which includes an amino acid sequence of a mimetic peptide of the apo B-100 epitope and in which a C-terminus of the mimetic

peptide is fused to an N-terminus of a helper T cell epitope.

An immunogen can be determined to be available as a vaccine having good efficacy by comparing the magnitude of responses to the immunogen and the ratio of observed individuals. In the present invention, with respect to the present object to provide a vaccine for preventing and treating obesity, the effect of an antigen on the induction of immune responses was assessed by investigating (a) body weight gain, (b) serum antibody titers and (c) changes in serum lipid profiles, thereby determining a highly efficient form of the antigen.

In detail, 100  $\mu$ g of each of purified PB1<sub>4</sub> and PB1<sub>4</sub>T peptides were intraperitoneally injected into 7-week-old SD white rats three times at 2-week intervals, and changes in body weight of the rats were observed and plotted on a graph (FIG. 15). From the primary injection to boosting (secondary injection), rats of each group showed similar body weight ranging from 292 g to 297 g. However, from one week after the secondary injection, a difference in body weight of rats was observed between vaccinated groups and normal and mock groups. This indicates that the weak immune responses induced by the primary injection were enhanced after boosting by the secondary injection, and that the enhanced immune responses lead to the suppression of body weight gain of rats. Compared to the normal and mock

groups, the vaccinated groups displayed a reduction in body weight increment. Also, the PB1<sub>4</sub>T peptide had a stronger inhibitory effect on body weight increment than the PB1<sub>4</sub> peptide (Table 2). This difference in body weight increment was maintained even after the third injection. In addition, the chimeric antigen PB1<sub>4</sub>T, which was homogenous, was found to more effectively induce immune responses than the PB1<sub>4</sub> peptide conjugated with a carrier protein, ovalbumin. In vaccinated SD white rats, serum antibody titers were measured at 10, 12, 14 and 16 weeks of age by ELISA (FIG. 16). The PB1<sub>4</sub>T-immunized group showed increased antibody titers relative to the PB1<sub>4</sub>-immunized group. At 14 weeks of age, the PB1<sub>4</sub>T-immunized group displayed 1.5-fold higher absorbancy (O.D.: optical density) values than the PB1<sub>4</sub>-immunized group. At 16 weeks of age, the PB1<sub>4</sub>-immunized group showed a reduction in antibody titer, whereas the PB1<sub>4</sub>T-immunized group maintained the increased antibody titers. With respect to serum lipids, the vaccinated groups displayed lower levels of TG and cholesterol than the normal and mock groups. In particular, LDL-cholesterol levels were reduced to 60% of normal levels (FIG. 17).

These results demonstrate that a fusion form of PB1<sub>4</sub> with a T cell epitope has higher immunogenicity than PB1<sub>4</sub> itself, which has a B cell epitope, and thus can be used in an effective vaccine composition.

In addition, the present inventors conducted a

clinical test with pet dog subjects for the efficacy of PB1<sub>4</sub>T. PB1<sub>4</sub>T was mixed with alumina and injected into ten pet dogs twice at 2-week intervals, and changes in body weight were observed. As a result, no increment in body weight was found in the pet dogs even when the dogs were allow to freely eat snacks and high-fat diets (Table 4). Also, when serum samples were collected from the immunized pet dogs after the secondary injection and serum antibody titers were measured by ELISA, high absorbance was found even when the serum samples were diluted 5,000-50,000 times, indicating that the PB1<sub>4</sub>T peptide has an excellent effect on the induction of antibody responses.

The anti-obesity vaccine of the present invention is composed of an antigen, a pharmaceutically acceptable carrier, a suitable adjuvant and other common materials, and is administered in an immunologically effective amount. The term "immunologically effective amount", as used herein, refers to an amount that is sufficient to exert the therapeutic and preventive effect on obesity and does not cause side effects or severe or excess immune responses. An accurate dosage may vary according to the specific immunogen to be administered, and may be determined by those skilled in the art using a known method for assaying the development of an immune response. Also, the dosage may vary depending on administration forms and routes, the recipient's age, health state and weight, properties and

degree of symptoms, types of currently received therapy, and treatment frequency. The carriers are known in the art and include a stabilizer, a diluent and a buffer. Suitable stabilizers include carbohydrates, such as sorbitol, lactose, mannitol, starch, sucrose, dextran and glucose, and proteins, such as albumin or casein. Suitable diluents include saline, Hanks' Balanced Salts and Ringer's solution. Suitable buffers include an alkali metal phosphate, an alkali metal carbonate and an alkali earth metal carbonate. The vaccine may also contain one or more adjuvants to enhance or strengthen immune responses. Suitable adjuvants include peptides; aluminum hydroxide; aluminum phosphate; aluminum oxide; and a composition that consists of a mineral oil, such as Marcol 52, or a vegetable oil and one or more emulsifying agents, or surface active substances such as lysolecithin, polycations and polyanions. The vaccine composition of the present invention may be administered as an individual therapeutic agent or in combination with another therapeutic agent, and may be co-administered either sequentially or simultaneously with a conventional therapeutic agent. The vaccine composition may be administered via known administration routes. Administration methods include, but are not limited to, oral, intradermal, intramuscular, intraperitoneal, intravenous, subcutaneous, and intranasal routes. Also, a pharmaceutical composition may be

administered using a certain apparatus, which can deliver an active material to target cells.

A better understanding of the present invention may be obtained through the following examples which are set forth to illustrate, but are not to be construed as the limit of the present invention.

## EXAMPLES

### Test Materials

A DNA miniprep kit and a kit used to extract DNA from a gel were purchased from Nucleogen, Bacto trypton, Bacto yeast extract, agar, etc. from Difco (Detroit, MI), restriction enzymes from Takara, and T4 DNA ligase from NEB. pBluescript II SK (Stratagene), PCR 2.1 (Invitrogen, Carlsbad, CA) and pQE30 (Qiagen) vectors and E. coli JM109 and M15 strains (Qiagen) were used.

IPTG used to induce protein production was purchased from Sigma, the Ni-NTA resin used to purify expressed proteins from Novagen, and the prestained marker used in SDS-PAGE, Western blotting, ECL, etc. from NEB. Urea used to denature proteins was purchased from Duchefa, and imidazole used in protein purification from USB. The membrane used in dialysis was MWCO 3,500 purchased from Spectrum, and the reagent used to prevent protein

aggregation was CHAPS from Amresco. The antibody used in ELISA was HRP-conjugated anti-rat IgG from Sigma. The substrate solution used in Western blotting and ECL was BCIP/NBT from Sigma, and the ECL Plus Western Blotting Detection Reagent was purchased from Amersham. Adjuvants used were Freund's adjuvant (Sigma) and aluminum hydroxide (Reheis). Protein concentration was determined by Pierce's BCA protein assay and Biorad's Bradford assay.

Tryglycerides, total cholesterol, HDL cholesterol and LDL cholesterol in the serum were measured using triglyzyme-V, cholestezyme-V, HDL-C555 (Shinyang Diagnostics, Korea) and EZ LDL cholesterol (Sigma), respectively. An LDL calibrator (Randox) was used.

5-week-old male Sprague Dawley (SD) white rats were purchased from Daehan Biolink Co. Ltd., Korea, and fed with a feedstuff from Samtako Inc., Korea, which contains more than 18% natural proteins, 5.3% crude fats, 4.5% crude fiber and 8.0% ash.

The following buffers were used to purify recombinant PB1<sub>4</sub>T and PB1<sub>4</sub> peptides: sonication disruption buffer (5 mM imidazole, 0.5 M NaCl, 20 mM Tris-Cl, pH 7.9), binding buffer (5 mM imidazole, 0.5 M NaCl, 20 mM Tris-Cl, 8 M urea, pH 7.9), washing buffer (50 mM imidazole, 0.5 M NaCl, 20 mM Tris-Cl, 8 M urea, pH 7.9), and elution buffer (400 mM imidazole, 0.5 M NaCl, 20 mM Tris-Cl, 8 M urea, pH 7.9).

**EXAMPLE 1: Preparation of an artificial gene for production of anti-obesity PB1<sub>4</sub>T peptide**

A pBluescript II SK vector was digested with BamHI and XhoI to obtain a B1<sub>4</sub> fragment, and a PCR 2.1 vector was  
5 digested with SalI and HindIII to obtain a T fragment. Since XhoI and SalI have compatible cohesive ends, the B1<sub>4</sub> and T fragments, obtained from the two vectors, were ligated using T4 DNA ligase at 16°C for 12 hrs. Since the  
ligated site is not digested by SalI or XhoI, SalI/HindIII  
10 digestion was carried out again to obtain a B1<sub>4</sub>T fragment. For protein expression, a pQE30 plasmid was selected as a vector system, which is designed to express a protein of interest in a form fused with six histidine residues to facilitate protein purification. The B1<sub>4</sub>T gene fragment was  
15 inserted into SalI/HindIII sites of the pQE30 vector. The resulting expression vector was designated "pB1<sub>4</sub>T" (FIG. 1). The expression vector was transformed into *E. coli* JM109. Plasmid DNA was isolated from the transformed cells and subjected to restriction mapping with SalI and HindIII. As  
20 a result, a 450 bp fragment was successfully inserted into the pQE30 vector (FIG. 2).

The recombinant vector pB1<sub>4</sub>T was deposited in the form of being transformed into *E. coli* (*E. coli* M15/pB1<sub>4</sub>T) at the Korean Culture Center of Microorganisms (KCCM, 361-  
25 221, Yurim B/D, Honje 1-dong, Sudaemum-gu, Seoul, Republic

of Korea) on March 4, 2004, and was assigned accession number KCCM-10562.

**EXAMPLE 2: Preparation of an artificial gene for production of anti-obesity PB1<sub>8</sub> peptide**

5           A pBluescript II SK vector was digested with SalI and  
and XhoI to obtain a B1<sub>4</sub> fragment. A pBX4 vector (pQE30  
vector having a B1<sub>4</sub> fragment insert, Korean Pat. Laid-open  
Publication No. 2002-0018971) was linearized by SalI  
digestion, and ligated with the B1<sub>4</sub> fragment using T4 DNA  
10          ligase at 16°C overnight.

**EXAMPLE 3: Nucleotide sequence determination of gene**

In order to confirm whether the B1<sub>4</sub>T gene fragment is  
correctly inserted in the pB1<sub>4</sub>T recombinant vector, the  
recombinant vector was prepared in a concentration of 300-  
15       500 ng/μg and subjected to DNA sequencing, which was  
performed by Core Bio System Co. Ltd., Korea. As a result,  
the selected recombinant vector was found to be a correct  
clone (FIG. 3).

**EXAMPLE 4: Recombinant peptide PB1<sub>4</sub>T expression**

20           The PB1<sub>4</sub>T and PB1<sub>8</sub> peptides were expressed from the

pQE30 vector, which initiates protein expression from its internal start codon along with six histidine residues for convenience of protein purification, followed by an enterokinase cleavage site. *E. coli* M15 was used as a host cell for peptide expression. The *E. coli* M15 strain was transformed with a recombinant vector and smeared onto LB plates containing ampicillin (Amp) and kanamycin (Kan). An emerged colony was cultured in 10 ml of LB medium containing Amp (100 µg/ml) and Kan (25 µg/ml) overnight. In order to investigate protein expression according to culture time, 1 ml of the overnight-cultured culture was inoculated in 50 ml of fresh LB medium. Then, the cells were incubated with agitation at 37°C for 1 hr 30 min, where OD at 600 nm was 0.4 to 0.5. At this state, IPTG was added to the medium at a final concentration of 1 mM, and the cells were further cultured for 5 hrs, during which 1 ml of the culture was collected every hour. Before IPTG addition, 1 ml of the culture was collected to be used as a non-induced control. The collected samples were centrifuged at 14,000 rpm for 1 min. The cell pellets were dissolved in 30 µl of 2×SDS sample buffer and subjected to SDS-PAGE. The results are given in FIGS. 4 and 5. The SDS-PAGE analysis revealed that PB1<sub>4</sub>T is 16.2 kDa and PB1<sub>8</sub> is 16.5 kDa.

**EXAMPLE 5: Western blotting for the recombinant peptide PB1<sub>4</sub>T**

The PB1<sub>4</sub>T peptide was identified by size analysis using SDS-PAGE, but in order to further confirm whether the expressed protein is PB1<sub>4</sub>T, Western blotting was carried out using two antibodies capable of recognizing PB1<sub>4</sub>T. As a  
5 control in Western blotting for PB1<sub>4</sub>T, *E. coli* M15 was transformed with the pQE30 vector not containing the B1<sub>4</sub>T fragment. Samples were collected before IPTG induction and three hours after IPTG induction. A rabbit anti-PB1<sub>4</sub> polyclonal antibody and a mouse anti-preS2 monoclonal  
10 antibody were 1:10000 diluted in PBS and used as primary antibodies. As secondary antibodies capable of recognizing the primary antibodies, peroxidase-conjugated goat anti-rabbit IgG and goat anti-mouse IgG were used after being 1:10000 diluted in PBS. A resulting blot was developed  
15 using an ECL Plus Western Blotting Kit. The blot was placed in a cassette, and a sheet of Fuji medical X-ray film was placed onto the blot. The blot was exposed to the film for 10 sec and developed. Since the rabbit anti-PB1<sub>4</sub> polyclonal antibody recognizes a PB1<sub>4</sub> fragment of PB1<sub>4</sub>T and the mouse  
20 anti-preS2 monoclonal antibody recognizes a T fragment of PB1<sub>4</sub>T, bands should be observed on both blots, which were individually incubated with each of the primary antibodies, when the PB1<sub>4</sub>T protein is correctly expressed. As shown in FIG. 8, the primary antibodies individually recognized PB1<sub>4</sub>  
25 and T of PB1<sub>4</sub>T, indicating that PB1<sub>4</sub>T is correctly

expressed.

**EXAMPLE 6: Evaluation of expression form of PB1<sub>4</sub>T and PB1<sub>8</sub> recombinant peptides in *E. coli***

In order to determine whether PB1<sub>4</sub>T and PB1<sub>8</sub> were  
5 expressed as soluble or insoluble proteins, the cells were  
harvested three hours after IPTG induction by  
centrifugation. The harvested cells were resuspended in  
sonication buffer and sonicated. The resulting pellet and  
supernatant were analyzed by SDS-PAGE. In detail, the cells  
10 treated with IPTG to induce protein expression were  
centrifuged at 9,000 rpm at 4°C for 30 min. The pelleted  
cells was frozen at -20°C for a while, thawed on ice, and  
resuspended in sonication disruption buffer (5 ml per 1 g  
pellet). The cells were sonicated fifteen times for 30 sec  
15 (each time with 1 min pause). The cell lysate was then  
centrifuged at 9,000 rpm at 4°C for 30 min. The supernatant  
was recovered, thus yielding a crude extract A containing  
unprocessed soluble proteins. Also, the pellet was  
recovered, thus giving a crude extract B containing  
20 unprocessed insoluble proteins. The crude extracts A and B  
were individually mixed with 2× SDS sample buffer, boiled  
at 95°C for 5 min, and electrophoresed on an SDS-PAGE gel.  
The SDS-PAGE analysis revealed that the target proteins  
were present mainly in the pellet rather than the

supernatant, indicating that the PB1<sub>4</sub>T and PB1<sub>8</sub> proteins are expressed in an insoluble form(FIGS 6 and 7).

**EXAMPLE 7: Purification of PB1<sub>4</sub>, PB1<sub>4</sub>T and PB1<sub>8</sub> recombinant peptides**

5           Peptide purification was carried out using Ni-NTA resin for histidine-tagged proteins. This purification is an affinity chromatographic method using the interaction between Ni<sup>+</sup> bound to the resin and the histidine hexamer at a terminal end of a fusion protein. After transformed E.  
10 coli cells were pre-cultured in 10 ml of LB medium overnight, the 10-ml culture was inoculated in 500 ml of LB medium and cultured at 37°C until OD at 600 nm reached 0.4 to 0.5. Then, 1 mM IPTG was added to the medium, and the cells were further cultured for 4 hrs. The cells were  
15 centrifuged at 9000 rpm for 30 min, and the cell pellet was placed at -20°C. After the frozen cells were thawed on ice, they were resuspended in sonication disruption buffer (5 ml/g of wet cells) and sonicated. The cell lysate was then centrifuged at 9000 rpm at 4°C for 30 min. The pellet was  
20 resuspended in a volume of binding buffer equal to that of the supernatant, sonicated three times to remove cell debris, and centrifuged at 9000 rpm at 4°C for 30 min. The thus obtained supernatant was subjected to affinity chromatography using Ni-NTA resin.

A column was 1 cm in diameter and 15 cm in height and was packed with 2 ml of a resin, and all of the steps were carried out at a flow rate of 2 ml/min. After the resin was packed into the column, the resin was washed with a three  
5 to five column volume of distilled water, and the resin was charged with  $\text{Ni}^{2+}$  using a five column volume of 1x charge buffer (50 mM  $\text{NiSO}_4$ ) and equilibrated with the binding buffer, thereby generating a Ni-chelate affinity column. After a sample was loaded onto the column twice, the column  
10 was washed with the binding buffer until the absorbance at 280 nm reached a baseline of 1.0 and then with washing buffer for 10 min. After the column was completely equilibrated, the column was eluted with elution buffer containing a higher concentration of imidazole than the  
15 washing buffer, thereby forming an imidazole gradient, and the elution was run alone through the column for a further 10 min to completely elute proteins bound to the resin. A total of twenty 2-ml fractions were collected. Since the eluted peptide was dissolved in 8 M urea, it was dialyzed  
20 in PBS overnight to remove urea.

As described above, since each protein was highly insoluble, it was purified after being denatured with a buffer containing 8 M urea, and proteins bound to the resin were eluted using an imidazole gradient of 50 mM to 400 mM.  
25 The results are given in FIGS. 9, 10 and 11. Most proteins were eluted at about 300 mM of imidazole. Protein yields

per 1 L culture were 3-3.5 mg for PB1<sub>8</sub> and 4-4.5 mg for PB1<sub>4</sub>T.

**EXAMPLE 8: Quantification of PB1<sub>4</sub>, PB1<sub>4</sub>T and PB1<sub>8</sub> recombinant peptides**

5           When the eluted PB1<sub>4</sub>T, PB1<sub>4</sub> and PB1<sub>8</sub> peptides were dialyzed in PBS, proteins were aggregated because urea was removed, thus forming precipitates. In this state, accurate protein concentrations could not be measured. The aggregation of the purified proteins was solved using 50 mM  
10 CHAPS. Protein concentrations were determined by a BCA protein assay and a Bradford assay. 2 mg/ml of BSA was serially diluted to 1000, 500, 250, 125 and 62.5 µg/ml, and the serial BSA dilutions were used as standard. The BCA assay was performed according to the protocol provided by  
15 Pierce. The BCA protein color reaction was carried out at 37°C for 30 min, and absorbance was then measured at 562 nm. Also, a sample was allowed to react with a Bradford reagent at room temperature for 10 min, and absorbance was then measured at 595 nm. Standard curves were obtained using the  
20 absorbance of serial dilutions of BSA or Bradford protein color reactions, and protein concentrations of samples were determined using the standard curves.

**EXAMPLE 9: Construction of pTBL<sub>4</sub> vector for PTBL<sub>4</sub> expression**

The pQE30 vector, transformed into *E. coli* M15, was double-digested with KpnI (Takara) and SalI (Takara) to excise a T cassette (preS2). A pBluescript plasmid was also treated with the same restriction enzymes. The excised T cassette and linearized pBluescript were separated on a gel, purified, and ligated with each other using T4 DNA ligase. 4  $\mu$ l of pBluescript, 4  $\mu$ l of T cassette, 1  $\mu$ l of T4 DNA ligase (MBI Fermentas, 1 Weiss u/ml) and 1  $\mu$ l of 10 $\times$  buffer (MBI Fermentas) were mixed in a 1.5-ml tube, and the ligation mixture was incubated at 16°C overnight. The recombined vector was then mixed with JM109 competent cells, heat-shocked at 42°C for 90 sec, and incubated in LB medium at 37°C for 1 hr. Then, the transformed cells were smeared onto LB/Amp plates and incubated at 37°C. Several colonies were randomly selected from the emerged colonies and cultured. Plasmid DNA was then isolated from the cultured cells, digested with restriction enzymes, and electrophoresed on an agarose gel to analyze the size of DNA fragments. An XhoI site in the T cassette was removed to obtain a TB<sub>4</sub> cassette. That is, since the T cassette (HBV preS2 gene, 183 bp) could not be used in cloning due to the XhoI site near its 3'-end (about 150 bp apart from the 5'-end of the T cassette), the T cassette was point-mutated at the internal XhoI site and thus had a new sequence. A short DNA fragment (30 bp) was excised from

pBluescript-preS2 due to the internal XhoI site of the T cassette. Synthetic oligomers were inserted into this position. To prevent self-ligation, the vector was treated with alkaline phosphatase (Boehringer Mannheim, GmbH, Germany) at 37°C for 30 min, dephosphorylated at 95°C for 5 min, and eluted from a gel. The oligomers were phosphorylated at their 5'-ends by treatment with polynucleotide kinase at 37°C for 30 min and 65°C for 20 min. Then, the vector and the oligomers were allowed to stand at 95°C for 5 min, and were slowly cooled in a heat block to be annealed. The oligomers and pBluescript-T were then treated with ligase at 16°C overnight. The recombined pBluescript-T was transformed into JM109 cells and smeared onto LB/Amp plates. After plasmid DNA was isolated from emerged colonies and analyzed, a clone carrying a desired plasmid was obtained. The oligomers consisted of 28 nucleotides corresponding to preS2, in which the fifth nucleotide, G, at the 5'-end of a sense-strand was replaced with A to remove XhoI site, thereby having a lysine substitution for arginine. Sense and anti-sense strands, each of which was designed to be 28 mer, were annealed and inserted into the XhoI-treated pBluescript-preS2. After the pBluescript-T was double-digested with SalI and XhoI and pQE30-B<sub>4</sub> was digested with SalI, they were purified from gels. The obtained T was inserted into the pQE30-B<sub>4</sub> cleaved at its 5'-end, thereby generating pQE30-pTB<sub>4</sub>. The recombined

TB<sub>4</sub> was confirmed by restriction mapping with SalI and HindIII. The thus obtained vector was designated pTB<sub>4</sub> (FIG. 13).

**EXAMPLE 10: Expression and purification of PTB<sub>4</sub>**

5           The expression vector pTB<sub>4</sub> was introduced into *E. coli* M15, and the transformed cells were cultured in 2 L of LB medium containing Amp and Kan. The cultured cells were centrifuged at 7000 rpm for 10 min, thus yielding 9 g of wet cells. Since the recombinantly expressed hybrid  
10 polypeptide PTB<sub>4</sub> had a His-tag, it was subjected to affinity chromatography using an Ni-NTA His-bound resin. A column used was 4 ml in resin volume, 1.8 cm in diameter and 8 cm in height. The absorbance range of an Econo system was 0.5, the paper speed of a recorder was 2 cm/hr, and the sample  
15 loading rate was 2 ml/min. First, the wet cells were suspended in sonication buffer, sonicated and centrifuged at 10,000 rpm at 4°C for 30 min. The pellet was dissolved in binding buffer and subjected to affinity chromatography. A binding solution flowed through the column to settle a  
20 resin. When a baseline was decided using a detector and a predetermined value was indicated, the sonicated sample was loaded onto the column. When the sample entered into the column and a predetermined value was indicated, a washing solution was run through the column. When a predetermined

value was indicated, an elution solution was run through the column, thereby isolating PTB1<sub>4</sub>. The expressed and purified hybrid polypeptide was analyzed by SDS-PAGE and Western blotting. The PTB1<sub>4</sub> separated on an SDS-PAGE gel was transferred onto a membrane by semi-dry transfer. The blot was incubated in blocking buffer (0.5% casein-phosphate buffered saline-Tween, 0.02% NaN<sub>3</sub>) at 37°C for 2 hrs, and washed with Tris-buffered saline-Tween (TBS-T, pH 7.6) twice for 2 min each washing. Then, the blot was incubated in a primary antibody at 37°C for 1 hr and washed with TBS-T four times for 5 min each time. The blot was incubated in a secondary antibody for 1 hr and washed according to the same method. To identify the T cassette, an anti-pres2 monoclonal antibody (1:10,000) and an HRP-conjugated goat anti-mouse IgG antibody (1:10,000) were used. A B cassette was detected using a rabbit anti-PB1<sub>4</sub> anti-serum (1:10,000) and an HRP-conjugated goat anti-rabbit IgG antibody (1:10,000). After being dried, the blot was treated with ECL reagents for 5 min to detect bands. As a result, in the B cassette, which was detected using the rabbit anti-PB1<sub>4</sub> anti-serum and the HRP-conjugated goat anti-rabbit IgG antibody, an about 16-kDa band was found in PB1<sub>4</sub>T and PTB1<sub>4</sub> samples. In the T cassette, which was detected using the anti-pres2 monoclonal antibody and the HRP-conjugated goat anti-mouse IgG antibody, a band of about 8 kDa was found in the PB1<sub>4</sub> sample, and a band of

about 16 kDa band was found in PB1<sub>4</sub>T and PTB1<sub>4</sub> samples. These results indicate that each hybrid polypeptide was accurately expressed and purified (FIG. 13).

**EXAMPLE 11: Conjugation of PB1<sub>4</sub> and ovalbumin**

5 PB1<sub>4</sub> was conjugated with a carrier protein, ovalbumin. The carrier protein and PB1<sub>4</sub> were mixed at a molar ratio of about 1:10, and allowed to react with agitation at 4°C for about 1 hr in a reaction vial. After the reaction mixture was supplemented with 2%  
10 glutaraldehyde, it was allowed to react for 3 hrs. The reaction mixture was then dialyzed using a dialysis membrane, MWCO 3,000, in PBS buffer overnight to remove remaining glutaraldehyde.

**EXAMPLE 12: Vaccination (Immunization)**

15 7-week-old SD white rats were divided into six groups and vaccinated (Table 1). As described in Table 1, 100 µg of each peptide, purified and quantified in Examples 7 and 10, was mixed with each adjuvant to give a final volume of 100 µl, and intraperitoneally injected into the rats.  
20 Injection was carried out three times at 2-week intervals, that is, at 7, 9 and 11 weeks of age. Freund's adjuvant and aluminum hydroxide were as adjuvants. The Freund's adjuvant

was used in the same amount as the peptide. Aluminum hydroxide of 5.8 mg/ml was adjusted to a final concentration of 0.2 mg/ml, mixed with each peptide, and incubated with agitation at room temperature. Blood samples were collected five days after the first boosting and five days, two weeks and four weeks after the second boosting.

TABLE 1  
Vaccination with peptides

	Normal	Mock	Test groups				
			A	B	C	D	E
Antigen	PBS	OVA	PBl <sub>4</sub> <sup>(+OVA)</sup>	PBl <sub>4</sub> T	PBl <sub>4</sub> <sup>(-OVA)</sup>	PBl <sub>8</sub>	PTBl <sub>4</sub>
Adjuvant		Aluminum hydroxide	Freund's adjuvant or aluminum hydroxide	Freund's adjuvant or aluminum hydroxide	Aluminum hydroxide	Aluminum hydroxide	Freund's adjuvant or aluminum hydroxide

Changes in body weight of SD rats after vaccination were plotted on a graph (FIG. 15). From the primary injection to boosting (secondary injection), rats of each group showed similar body weight ranging from 292 g to 297 g. However, from one week after the secondary injection, a difference in body weight of rats was observed between vaccinated groups and normal and mock groups. At 18 weeks of age, compared to the mock groups, the PBl<sub>4</sub>-vaccinated group showed a difference of 16 g in body weight, and the PBl<sub>4</sub>T-vaccinated group displayed a difference of 27 g in body weight (Table 2). This indicates that the weak immune responses induced by the primary injection were enhanced

after boosting by the secondary injection, that and the enhanced immune responses lead to the suppression of body weight increment of rats. This difference in body weight increment was maintained even after the third injection.

5

TABLE 2

Changes in body weight of SD rats after vaccination

Age (wk)	Normal	Mock	PB1 <sub>4</sub> <sup>+OVA</sup>	PB1 <sub>4</sub> T	PTB1 <sub>4</sub>

14	407±14	407±8	395±8	391±12	396±10
15	413±16	414±9	403±11	397±10	401±10
16	422±18	424±10	414±13	406±10	412±10
17	436±22	435±11	425±14	415±9	420±9
18	456±24	452±11	436±12	425±9	433±11

In Table 2, all data are represented as mean±SD, wherein SD (standard deviation) was calculated for five SD white rats, and units are grams.

10

### EXAMPLE 13: Measurement of antibody titers

15

Antibody titers were measured using serum samples by indirect ELISA. 100 µl (100 ng) of PB1<sub>4</sub> was placed into each well of a microtiter plate. The plate was incubated at 4°C overnight, and incubated in a blocking solution (PBS, 0.5% casein, 0.02% NaN<sub>3</sub>) at 37°C for 1 hr. Each well was

washed with PBST three times. Serum samples collected from vaccinated SD rats were 1:500 to 1:8000 diluted in PBS. 100  $\mu$ l of each diluted serum sample was added to each well, and incubated at 37°C for 1 hr. Each well was washed with PBST  
5 three times and incubated with a 1:1000 dilution of goat anti-rat IgG as a secondary antibody. The plate was subjected to color development with OPD, and absorbance was measured at 450 nm.

FIG. 16 shows the antibody titers of SD rats of vaccinated groups at 10, 12, 14 and 16 weeks of age. Titers  
10 were determined by ELISA based on the absorbance value of 0.6 when each serum sample was 1:2000 diluted. When the serum sample was diluted at 1:500 to 1:8000, the groups injected with PB1<sub>4</sub>, PB1<sub>4</sub>T and PTB1<sub>4</sub> showed increased  
15 antibody titers until 14 weeks of age. The PB1<sub>4</sub>T-immunized group displayed 1.5-fold higher O.D. values than the PB1<sub>4</sub>-immunized group, and the PTB1<sub>4</sub>-immunized group showed a slight increase compared to the PB1<sub>4</sub> group. At 16 weeks of age, the PB1<sub>4</sub> group showed a reduction in antibody titer,  
20 and the PB1<sub>4</sub>T and PTB1<sub>4</sub> groups maintained the increase of antibody titers. However, PTB1<sub>4</sub> was found to have a remarkably weak effect in increasing antibody titers by about 50-60% compared to PB1<sub>4</sub>T.

#### **EXAMPLE 14: Evaluation of serum lipid profiles**

TG and cholesterol levels were measured as follows. 4  $\mu$ l of a serum sample were mixed with 200  $\mu$ l of a development reagent and incubated at 37°C for 5 min, and absorbance was then measured at 505 nm and 500nm. To measure HDL levels, a serum sample was mixed with a precipitation reagent at a ratio of 1:1, allowed to stand at room temperature for 10 min, and centrifuged at over 3000 rpm for 10 min. 4  $\mu$ l of the centrifugal supernatant was mixed with 200  $\mu$ l of a development reagent and incubated at 37°C for 5 min, and absorbance was then measured at 555 nm. LDL-cholesterol levels were measured using an EZ LDL cholesterol kit (Sigma) and an LDL calibrator (Randox). According to the protocol supplied by the manufacturer, 4  $\mu$ l of a serum sample was mixed with 1,150  $\mu$ l of a reagent contained in the kit, incubated at 37°C for 5 min, supplemented with 250  $\mu$ l of the reagent, and incubated again at 37°C for 5 min. Then, absorbance was measured at 600 nm. Serum levels of each lipid were determined using measured absorbance and a standard curve was obtained using standard solutions.

The test results for lipid profiles in serum samples collected five weeks after the third injection into SD rats are given in Table 3, below.

TABLE 3

Serum lipid profiles

	TG	HDL-cholesterol	Total cholesterol	LDL-cholesterol
Normal	102.3±5.6	51.5±2.7	110.2±6.5	47.7±9.5
Mock	98.0±5.9	54.6±7.8	104.1±3.9	42.9±9.1
PB1 <sub>4</sub> <sup>+OVA</sup>	92.5±4.5	41.7±4.3	94.6±7.1	34.8±4.0
PB1 <sub>4</sub> T	90.3±6.2	43.0±2.5	97.6±2.3	33.0±4.3

In Table 3, all data are represented as mean±SD, wherein SD (standard deviation) was calculated for five SD white rats, and units are mg/dl.

The normal and mock groups displayed levels of TG and cholesterol about 10 mg/ml (10 mg/100 ml) higher than the vaccinated groups. When the vaccinated groups were compared with each other, higher levels of TG and LDL-cholesterol were found in the PB1<sub>4</sub>-vaccinated group but the difference was negligible (FIG. 17).

#### 10 **EXAMPLE 15: Clinical test with pet dog subjects**

PB1<sub>4</sub>T was mixed with alumina as an adjuvant. 0.5 ml of the mixture (2 mg/ml) was intramuscularly or subcutaneously injected into ten pet dogs (managed with an obesity treatment in an animal hospital in Ansan, Korea) twice at 2-week intervals. Changes in body weight of the dogs were observed for a period of 1.5 to 3 months. As a result, an antibody was slowly reduced (half-life: three months), and no increase in body weight was found in the pet dogs even when the dogs were allow to freely eat snacks and high-fat foods. In detail, the body weight increment

was suppressed in all of the ten pet dogs even when the dogs digested snacks and high calorie foods. In particular, Yorkshire Terriers did not increase body weight when injected with PB1<sub>4</sub>T even in the situation in which the body weight of the dog was predicted to increase according to the dog's sex and age.

In addition, serum samples were collected from the immunized pet dogs to assess the induction degree of antibody responses. One week after the secondary injection, serum titers of an antibody to PB1<sub>4</sub>T and PB1<sub>4</sub> were measured by ELISA. A high absorbance of 0.5 was found even when the serum samples were diluted 5,000-50,000 times, indicating that the PB1<sub>4</sub>T peptide has an excellent effect on the induction of antibody responses.

15

TABLE 4

Changes in body weight after vaccination

Species	Sex	Age (year)	Body weight (kg) for the test period (wk)					Diet
			0	2	4	8	12	
Shih Tzu	F	4.4	5.5	5.2	5.5	5.3	5.3	High-calorie
Maltese	F	8	4.3	4.0	4.2			Normal
Poodle	F	7.4	4.7	4.7	4.6			Low-calorie
Poodle	F	6.1	4.5	4.5	4.4			Low-calorie
Yorkshire Terrier	F	4	5.9	5.6	5.6			Normal
Yorkshire Terrier	F	15	8.7	8.8	8.6			High-calorie
Yorkshire Terrier	F	3.7	3.8	3.8	3.7			High-calorie
Yorkshire Terrier	M	5.1	4.8	4.8	4.7			Normal

Yorkshire Terrier	M	2.5	3.3	3.4	3.3			High-calorie
Miniature Pinscher	M	5.1	3.6	3.5	3.5			High-calorie
Miniature Schunauzer	F	1.4	7.2	7.0	7.0			Normal

### Industrial Applicability

As described hereinbefore, the hybrid polypeptide of the present invention, in which a C-terminus of a mimetic peptide of a B cell epitope of apo B-100 having an anti-obesity effect is fused to an N-terminus of a helper T cell epitope, displays an excellent anti-obesity activity without inducing immune responses that neutralize beneficial activities or effects of the B cell epitope of apolipoprotein B-100 or without causing harmful side effects. Therefore, the hybrid polypeptide is very useful in preventing or treating obesity.

BUDAPEST TREATY ON THE INTERNATIONAL  
RECOGNITION OF THE DEPOSIT OF MICROORGANISMS  
FOR THE PURPOSES OF PATENT PROCEDURE

INTERNATIONAL FORM

<p>To. Hyo Joon Kim HBI 604, Hanyang University Sa-1-dong, Sangrok-gu, Ansan Gyeonggi-do, 425-791 South Korea</p>	<p>RECEIPT IN THE CASE OF AN ORIGINAL issued pursuant to Rule 7.1 by the INTERNATIONAL DEPOSITARY AUTHORITY identified at the bottom of this page</p>
---	---

<b>I. IDENTIFICATION OF THE MICROORGANISM</b>	
Identification reference given by the DEPOSITOR : M15/pB1 <sub>4</sub> T	Accession number given by the INTERNATIONAL DEPOSITARY AUTHORITY: KCCM-10562
<b>II. SCIENTIFIC DESCRIPTION AND/OR PROPOSED TAXONOMIC DESIGNATION</b>	
The microorganism identified under I above was accompanied by: <input type="checkbox"/> a scientific description <input type="checkbox"/> a proposed taxonomic designation (Mark with a cross where applicable)	
<b>III. RECEIPT AND ACCEPTANCE</b>	
This International Depositary Authority accepts the microorganism identified under I above, which was received by it on Mar. 4, 2004. (date of the original deposit) <sup>1</sup>	
<b>IV. INTERNATIONAL DEPOSITARY AUTHORITY</b>
